## Topological Data Analysis

Topology describes, characterizes, and discriminates shapes by studying their properties that are preserved under continuous deformations, such as stretching and bending, but not tearing or gluing

## Topological Data Analysis

Assumption in TDA: Any data can be endowed with a shape.
So, any data can be studied in terms of its topological features

Data Structures

## The Notion of Shape

## Geometry or Topology?

Which of these domains look similar?

## Geometry or Topology?

## And what about these ones?

## Geometry or Topology?

The answer depends on the point of view we adopt

Geometry cares about those properties which change when an object is continuously deformed
E.g. length, area, volume, angles, curvature, ...

## Geometry or Topology?

The answer depends on the point of view we adopt

Topology
Ged etry cares about those properties which change when an object is continuously deformed
E.g. connectivity, orientation, manifoldness, ...

## Homeomorphisms

## Definition:

Given two topological spaces $(X, T)$ and $\left(X^{\prime}, T^{\prime}\right)$,
a function $\mathrm{f}: \mathrm{X} \longrightarrow \mathrm{X}^{\prime}$ is called homeomorphism if:

* fis a bijection
* f is continuous
* $f^{-1}$ is continuous

Two topological spaces ( $\mathrm{X}, \mathrm{T}$ ) and ( $\mathrm{X}^{\prime}, \mathrm{T}^{\prime}$ ) are homeomorphic and denoted $X \cong X^{\prime}$ if there exists a homeomorphism $\mathrm{f}: \mathrm{X} \rightarrow \mathrm{X}^{\prime}$

Homeomorphisms induce an equivalence relation of topological spaces partitioning them into equivalence classes

## Homeomorphisms

## Intuitively:

The notion of homeomorphism captures the idea of continuous deformation

2ll

## Homeomorphisms

* No Glue

## Topological Invariants

## Definition:

$I$ is a topological invariant if, given two topological spaces $(X, T)$ and $\left(X^{\prime}, T^{\prime}\right)$,

Some classical topological invariants:

* Connectedness
+ Compactness
+ Manifoldness

* Orientability
+ Euler characteristic
+ Homology
+ Homotopy

## Topological Invariants

## Question:

Is there a "perfect" topological invariant I such that

$$
X \cong X^{\prime} \text { if and only if }\|(X)=\|\left(X^{\prime}\right) ?
$$

## Topological Invariants

## Question:

Is there a "perfect" topological invariant I such that

$$
X \cong X^{\prime} \text { if and only if }\|(X)=\|\left(X^{\prime}\right) ?
$$

Let us simplify the question and let focus on:

* Considering a specific topological invariant I (e.g. the homology)
* Completely characterizing just the spheres $S^{n}:=\left\{x \in \mathbb{R}^{n}:|x|=1\right\}$

The above question turns into the following:
If $X$ and $S^{n}$ have the same homology, then $X \cong S^{n}$ ?

## Topological Invariants

## Question:

Is there a "perfect" topological invariant I such that

$$
X \cong X^{\prime} \text { if and only if }\|(X)=\|\left(X^{\prime}\right) ?
$$

Let us simplify the question and let focus on:

* Considering a specific topological invariant I (e.g. the homology)
* Completely characterizing just the spheres $S^{n}:=\left\{x \in \mathbb{R}^{n}:|x|=1\right\}$

The above question turns into the following:
If $X$ and $S^{n}$ have the same homology, then $X \cong S^{n}$ ?

## Topological Invariants

## But:

Replacing homology with homotopy, the answer is positive!

## Topological Invariants

## But:

Replacing homology with homotopy, the answer is positive!

Poincaré Conjecture (3rd Millennium Prize Problem):

If $X$ is a closed $n$-manifold homotopy equivalent to $S^{n}$, then $X \cong S^{n}$

Proven by Grigori Perelman in 2003

## Topological Invariants

## But:

Replacing homology with homotopy, the answer is positive!

Poincaré Conjecture (3rd Millennium Prize Problem):

If $X$ is a closed $n$-manifold homotopy equivalent to $S^{n}$, then $X \cong S^{n}$

Proven by Grigori Perelman in 2003

## Topological Invariants

## But:

Replacing homology with homotopy, the answer is positive!

Poincaré Conjecture (3rd Millennium Prize Problem):

If $X$ is a closed n-manifold homotopy equivalent to $S^{n}$, then $X \cong S^{n}$

Proven by Grigori Perelman in 2003

So:
Why we will mainly focus on homology rather than homotopy?

## Topological Invariants

## But:

Replacing homology with homotopy, the answer is positive!

Poincaré Conjecture (3rd Millennium Prize Problem):

If $X$ is a closed $n$-manifold homotopy equivalent to $S^{n}$, then $X \cong S^{n}$

So:
Why we will mainly focus on homology rather than homotopy?

Because, in practice, computing homotopy groups is nearly impossible!

## Simplicial Complexes

## Complexes \& Data

## Goal:

We want to associate a topological structure to a given dataset

Data

Shape

Due to the nature of data and to our computational ambitions, datasets will be represented by "discrete" structures

Among various possibilities, simplicial complexes represent the most suitable choice

In fact, simplicial complexes are able to deal with data:

* of large size (e.g. consisting of a huge number of samples)
* of high dimension (e.g. involving a large number of variables or parameters)
* unorganized (e.g. not arranged in a regular grid)

## Simplicial Complexes

## Definitions:

A set $V:=\left\{v_{0}, v_{1}, \ldots, v_{k}\right\}$ of points in $\mathbb{R}^{n}$ is called
 geometrically independent if vectors $\mathrm{v}_{1}-\mathrm{v}_{0}, \ldots, \mathrm{v}_{\mathrm{k}}-\mathrm{v}_{0}$ are linearly independent over $\mathbb{R}$
E.g. two distinct points, three non-collinear points, four non-coplanar points

The $\boldsymbol{k}$-simplex $\sigma=\boldsymbol{v}_{0} \boldsymbol{v}_{1} \ldots \boldsymbol{v}_{k}$ spanned by a geometrically independent set $\mathrm{V}=\left\{\mathrm{v}_{0}, \mathrm{v}_{1}, \ldots, \mathrm{v}_{\mathrm{k}}\right\}$ of in $\mathbb{R}^{n}$ is the convex hull of $V$, i.e. the set of all points $x \in \mathbb{R}^{n}$ such that

$$
x=\sum_{i=0}^{k} t_{i} v_{i} \text { where } \sum_{i=0}^{k} t_{i}=1 \quad \text { and } \mathrm{t}_{\mathrm{i}} \geq 0 \text { for all } \mathrm{i}
$$

The numbers $\mathrm{t}_{\mathrm{i}}$ are uniquely determined by x and are called barycentric coordinates of x E.g. a 0 -simplex is a vertex, a 1 -simplex is an edge, a 2 -simplex is a triangle, a 3 -simplex is a tetrahedron

## Simplicial Complexes

## Definitions:

+ The points $\mathrm{v}_{0}, \mathrm{v}_{1}, \ldots, \mathrm{v}_{\mathrm{k}}$ spanning a k -simplex $\sigma$ are called the vertices of $\sigma$
* k is called the dimension of $\sigma$ and denoted as $\operatorname{dim}(\sigma)$
+ Any simplex $\tau$ spanned by a non-empty subset of V is called a face of $\sigma$
+ Conversely, $\sigma$ is called a coface of $\tau$

## Simplicial Complexes

## Definition:

A (geometric) simplicial complex $K$ in $\mathbb{R}^{n}$ is a collection of simplices in $\mathbb{R}^{n}$ such that

* Every face of a simplex of $K$ is in $K$
* The non-empty intersection of any two simplices of $K$ is a face of each of them

simplicial complex

non-simplicial complex

## Simplicial Complexes

## Definitions:

Given a (geometric) simplicial complex $K$ in $\mathbb{R}^{n}$,

* The dimension of a simplicial complex K in $\mathbb{R}^{n}$, denoted as $\operatorname{dim}(K)$, is the supremum of the dimensions of the simplices of $K$

* A simplex $\sigma$ of $K$ such that $\operatorname{dim}(\sigma)=\operatorname{dim}(K)$ is called maximal
* A simplex $\sigma$ of $K$ which is not a proper face of any simplex of $K$ is called top
* A subcollection of $K$ that is itself a simplicial complex is called a subcomplex of $K$

## Simplicial Complexes

## Definitions:

Given a simplex $\sigma$ of a (geometric) simplicial complex $K$ in $\mathbb{R}^{n}$,

* The star of $\sigma$ is the set $S t(\sigma)$ of the cofaces of $\sigma$
* The link of $\sigma$ is the set $L k(\sigma)$ of the faces of the simplices in $\operatorname{St}(\sigma)$ such that do not intersect $\sigma$

## Simplicial Complexes

## Definitions:

Given a simplex $\sigma$ of a (geometric) simplicial complex $K$ in $\mathbb{R}^{n}$,

* The star of $\sigma$ is the set $S t(\sigma)$ of the cofaces of $\sigma$
* The link of $\sigma$ is the set $L k(\sigma)$ of the faces of the simplices in $\operatorname{St}(\sigma)$ such that do not intersect $\sigma$

## Simplicial Complexes

Given a (geometric) simplicial complex $K$ in $\mathbb{R}^{n}$, its polytope $|K|$ is the subset of $\mathbb{R}^{n}$ defined as the union of the simplices of $K$

The polytope $|K|$ can be endowed with two possible topologies $T_{1}$ and $T_{2}$ :
$\star T_{1}$ : A subset F of $|\mathrm{K}|$ is a closed set of $\left(|\mathrm{K}|, \mathrm{T}_{1}\right)$ if and only if $\mathrm{F} \cap \sigma$ is a closed set of $\left(\sigma, T_{\sigma}\right)$ for each $\sigma$ in $K$ where $T_{\sigma}$ is the subspace topology induced on $\sigma$ by $\mathbb{E}^{n}$
${ }^{*} T_{2}$ : The subspace topology induced on $|K|$ by $\mathbb{E}^{n}$
In general, the two topologies $\mathrm{T}_{1}, \mathrm{~T}_{2}$ are different, but

Proposition: If $K$ is a finite simplicial complex, $T_{1}=T_{2}$
From now on, if not differently specified, we consider only finite simplicial complexes

## Simplicial Complexes

## Proposition:

Given a simplicial complex $K$ and a topological space $(X, T)$, a function from (|K|, $T_{1}$ ) to $(X, T)$ is continuous if and only if $f l_{\sigma}$ is continuous for each $\sigma \in K$

## Definition:

Given two simplicial complexes $K$ and $K^{\prime}$,

* A function $f: K \rightarrow K^{\prime}$ is called a simplicial map if for every simplex $\sigma=v_{0} \mathrm{~V}_{1} \ldots \mathrm{v}_{\mathrm{k}}$ in K , $f(\sigma)=f\left(v_{0}\right) f\left(v_{1}\right) \ldots f\left(v_{k}\right)$ is a simplex in $K^{\prime}$
* The restriction $f_{v}$ of $f$ to the set of vertices $V$ of $K$ is called the vertex map of $f$

## Simplicial Complexes

## Definition:

An abstract simplicial complex K on a set V is a collection of finite non-empty subsets of V , called simplices, such that if $\sigma \in \mathrm{K}$ and $\tau \subseteq \sigma$, then $\tau \in \mathrm{K}$ Analogously to the case of a geometric simplicial complex,

* The elements of V are called vertices of K
* The dimension of a simplex $\sigma$ is one less than the number of its elements
* The supremum of the dimensions of the simplices in $K$ is called dimension of $K$
* Each non-empty subset $\tau$ of a simplex $\sigma \in \mathrm{K}$ is called a face of $\sigma$ and $\sigma$ is called a coface of $\tau$

The notions of geometric simplicial complex and abstract simplicial complex are equivalent. More properly, it is always possible,

* Given an abstract simplicial complex, to endow it with a geometric realization
* Given a geometric simplicial complex, to forget its geometry thus obtaining an abstract simplicial complex

## Simplicial Complexes

## Definition: A simplicial complex K is called

* n-manifold [with boundary] if its polytope $|\mathrm{K}|$ is a (topological) n-manifold [with boundary]
* Combinatorial n-manifold [with boundary] if, for every vertex v, the link Lk(v) is homeomorphic to the ( $n-1$ )-sphere $S^{n-1}$ [or to the ( $n-1$ )-disk $\left.D^{n-1}:=\left\{x \in \mathbb{R}^{n-1}:|x| \leq 1\right\}\right]$

If $K$ is a combinatorial n-manifold [with boundary], then $K$ is a $n$-manifold [with boundary]
The converse is:
True for $n \leq 3$
Open for $n=4$
False for $n>4$

## Regular Grids

## Hyper-Cube:

A $\boldsymbol{k}$-hyper-cube $\boldsymbol{\eta}$ is the Cartesian product of $k$ closed intervals of equal length

## Regular Grids:

A regular grid $H$ is a (finite) collection of hyper-cubes such that:

* Each face of a hyper-cube of H is in H
* Each non-empty intersection of two hyper-cubes in H is a face of both
* The domain of H is a hyper-cube

## Cell Complexes

## Intuitively:

Similarly to simplicial complexes and regular grids,

> A cell complex 「 is a collection of cells "suitably glued together"

Where a $k$-cell is a topological space homeomorphic to the $k$-dimensional open disk $i\left(D^{k}\right)$

## Bibliography

## Simplicial Homology

## Simplicial Homology

Given a topological space $X$, the homology of $X$ is a topological invariant
detecting the "holes" of $X$
capturing the independent non-bounding cycles of $X$
measuring how far the chain complex associated with $X$ is from being exact

$$
\longmapsto H_{k}(X ; \mathbb{Z}) \cong \begin{cases}\mathbb{Z} & \text { for } k=0 \\ \mathbb{Z}^{6} & \text { for } k=1 \\ \mathbb{Z} & \text { for } k=2 \\ 0 & \text { otherwise }\end{cases}
$$

## Simplicial Homology

## Simplicial Homology

Given a simplicial complex K,

* a $k$-chain is a formal sum (with $\mathbb{Z}_{2}$ coefficients) of $k$-simplices of $K$

## Examples:

$+a+b+e$ is a 0-chain

+ $f g+d g+d e+e g$ is a 1-chain
* $a b g+a f g$ is a 2-chain

## Simplicial Homology

The chain complex $\boldsymbol{C}_{*}(\boldsymbol{K})$ associated with $K$ consists of:

* a collection $\left\{C_{k}(K)\right\}_{k \in \mathbb{Z}}$ of vector spaces where $C_{k}(K)$ is the group of the $k$-chains of $K$
* a collection $\left\{\partial_{k}\right\}_{k \in \mathbb{Z}}$ of linear maps where the boundary map $\partial_{k}: C_{k}(K) \longrightarrow C_{k-1}(K)$ is defined by

$$
\partial_{k}\left(v_{0} \cdots v_{k}\right):=\sum_{i=0}^{k} v_{0} \cdots \hat{v}_{i} \cdots v_{k}
$$

## Simplicial Homology

## Examples:

$+\partial_{1}(a b)=a+b$
${ }^{+} \partial_{1}(a b+b c)=a+2 b+c=a+c$

* $\boldsymbol{\partial}_{\mathbf{2}}(a f g+e f g)=a f+a g+2 f g+e f+e g=$
$=a f+a g+e f+e g$
+ $\partial_{1}(a f+a g+e f+e g)=$
$=2 a+2 f+2 g+2 e=0$

## Simplicial Homology

## Properties:

* For $k<0$ or $k>\operatorname{dim}(K), C_{k}(K)$ is the null group
* For $k \leq 0$ or $k>\operatorname{dim}(K), \partial_{k}$ is the null map
* For any $k \in \mathbb{Z}, \partial_{k} \circ \partial_{k+1}=0$
$\star$ For any $k \in \mathbb{Z}, \operatorname{Im}\left(\partial_{k+1}\right) \subseteq \operatorname{Ker}\left(\partial_{k}\right)$

## Simplicial Homology

## Definition:

A k-chain c is called:

* $k$-cycle if $\mathrm{c} \in \operatorname{Ker}\left(\partial_{\mathrm{k}}\right)$
+ $k$-boundary if $\mathrm{c} \in \operatorname{Im}\left(\mathrm{d}_{\mathrm{k}+1}\right)$

Each k-boundary is a k-cycle

## Simplicial Homology

Given a simplicial complex $K$, the $k$-homology group $\boldsymbol{H}_{k}(K)$ of $K$ is defined as

$$
H_{k}(K):=Z_{k}(K) / B_{k}(K)
$$

where:
$\leftrightarrow Z_{k}(K)$ is the group of $k$-cycles of $K$

* $B_{k}(K)$ is the group of $k$-boundaries of $K$

## Simplicial Homology

$H_{k}(K)$ partitions the $k$-cycles into equivalence classes called homology classes

## Definition:

Two k-cycles are said homologous
if they belong to the same
homology class or, equivalently, if their difference is a $k$-boundary

## Simplicial Homology

Each homology group can be expressed as

$$
H_{k}(K) \cong\left(\mathbb{Z}_{2}\right)^{\beta_{k}}
$$

$$
H_{k}(K) \cong \begin{cases}\mathbb{Z}_{2} & \text { for } k=0 \\ \left(\mathbb{Z}_{2}\right)^{6} & \text { for } k=1 \\ \mathbb{Z}_{2} & \text { for } k=2\end{cases}
$$

$\beta_{k}$ is called the $k^{\text {th }}$ Betti number of $K$

## Simplicial Homology

## Examples:

+ point $P$

$$
\beta_{k}(P)= \begin{cases}1 & \text { for } k=0 \\ 0 & \text { for } k>0\end{cases}
$$

* n-dimensional sphere $S^{n}$

$$
\beta_{k}\left(S^{n}\right)= \begin{cases}1 & \text { for } k=0 \\ 0 & \text { for } 0<k<n \\ 1 & \text { for } k=n \\ 0 & \text { for } k>n\end{cases}
$$

$$
\beta_{k}(T)= \begin{cases}1 & \text { for } k=0 \\ 2 & \text { for } k=1 \\ 1 & \text { for } k=2 \\ 0 & \text { for } k>2\end{cases}
$$

## Simplicial Homology

Homology groups can be defined in a more general way by choosing coefficients in $\mathbb{Z}$

## Theorem:

Each homology group can be expressed as

$$
H_{k}(K ; \mathbb{Z}) \cong \mathbb{Z}^{\beta_{k}}\left\langle c_{1}, \ldots, c_{\beta_{k}}\right\rangle \oplus \mathbb{Z}_{\lambda_{1}}\left\langle c_{1}^{\prime}\right\rangle \oplus \cdots \oplus \mathbb{Z}_{\lambda_{p_{k}}}\left\langle c_{p_{k}}^{\prime}\right\rangle
$$

with $\lambda_{i+1} \mid \lambda_{i}$

We call:

* $\beta_{k}$, the $k^{\text {th }}$ Betti number of $K$
${ }^{\star} \lambda_{1}, \ldots, \lambda_{p_{k}}$, the torsion coefficients of $K$
${ }^{\star} c_{1}, \ldots, c_{\beta_{k}}, c_{1}^{\prime}, \ldots, c_{p_{k}}^{\prime}$, the homology generators of K

## Simplicial Homology

## Working with coefficients in $\mathbb{Z}$ :

Up to isomorphism, the Betti numbers and the torsion coefficients of $K$ completely characterize the homology groups of $K$

Working with coefficients in a field $\mathbb{F}$ :

Up to isomorphism, the Betti numbers of $K$ completely characterize the homology groups of $K$

## Simplicial Homology

## Example:

The Klein bottle $\boldsymbol{K}$ is a non-orientable 2-dimensional manifold embeddable in $\mathbb{R}^{4}$ which can be built from a unit square by the following construction

## Simplicial Homology

## Example:

By considering $\mathbb{Z}$ as coefficient group,
K has the following homology groups

$$
H_{k}(K ; \mathbb{Z}) \cong \begin{cases}\mathbb{Z} & \text { for } k=0 \\ \mathbb{Z} \oplus \mathbb{Z}_{2} & \text { for } k=1 \\ 0 & \text { for } k \geq 2\end{cases}
$$

So, it can be distinguished from a torus T

$$
H_{k}(T ; \mathbb{Z}) \cong \begin{cases}\mathbb{Z} & \text { for } k=0 \\ \mathbb{Z}^{2} & \text { for } k=1 \\ \mathbb{Z} & \text { for } k=2 \\ 0 & \text { for } k>2\end{cases}
$$

## Simplicial Homology

## Example:

By considering $\mathbb{Z}_{2}$ as coefficient group,
the Klein bottle K and the torus T have isomorphic homology groups

## Bibliography

## Some References:

+ Simplicial Homology:
\% J. R. Munkres. Elements of algebraic topology. CRC Press, 1984.

## From Data to Complexes

## From Data to Complexes

Let us consider a dataset represented by a finite point cloud $V$ in $\mathbb{R}^{n}$

Studying the shape of V just by considering the space consisting of its points does not provide any relevant topological information

The "real" shape of the dataset can be captured by properly constructing a complex connecting together close points through simplices

## From Data to Complexes

## Standard Constructions:

A number of possible choices have been introduced in the literature:

+ Delaunay triangulations
* Voronoi diagrams
+ Čech complexes
* Vietoris-Rips complexes
+ Alpha-shapes
* Witness complexes

Most of the above constructions are based on the notion of Nerve complex

## From Data to Complexes

## A First Classification:

Given a finite point cloud $V$ in $\mathbb{R}^{n}$,

| Delaunay | Output Complex | Dimension | Dependence on a <br> Parameter |
| :---: | :---: | :---: | :---: |
| Griangulation | Geometric | $n$ | X |
| Čech complex | Abstract | Arbitrary <br> (up to $/ V /-1)$ |  |
| Vietoris-Rips <br> complex | Abstract | Arbitrary <br> (up to $/ V /-1)$ |  |
| Alpha-shapes | Geometric | $n$ |  |
| Witness complexes | Abstract | Arbitrary <br> (upto $/ V /-1$ ) |  |

## Nerve Complexes

## Definition:

Given a finite collection $S$ of sets in $\mathbb{R}^{n}$,
The nerve $\operatorname{Nrv}(S)$ of $S$ is the abstract simplicial complex generated by the non-empty common intersections

Formally,

$$
\operatorname{Nrv}(S):=\left\{\sigma \subseteq S \mid \bigcap_{s \in \sigma} s \neq \emptyset\right\}
$$

## Nerve Complexes

## Definition:

Given a finite collection $S$ of sets in $\mathbb{R}^{n}$,
The nerve $\operatorname{Nrv}(S)$ of $S$ is the abstract simplicial complex generated by the non-empty common intersections

Formally,

$$
\operatorname{Nrv}(S):=\left\{\sigma \subseteq S \mid \bigcap_{s \in \sigma} s \neq \emptyset\right\}
$$

## Nerve Complexes

## Nerve Theorem:

If $S$ is a finite collection of convex sets in $\mathbb{R}^{n}$, then the nerve of $S$ and the union of the sets in S are homotopy equivalent (and so they have the same homology)

## Nerve Complexes

Nerve Theorem can be generalized by replacing the convexity of sets in S with the request that all non-empty common intersections are contractible (i.e. that can be continuously shrunk to a point)

## Original Nerve Theorem:

If $S$ is an open cover of a (para)compact space $X$ such that every non-empty intersection of finitely many sets in $S$ is contractible, then $X$ is homotopy equivalent to the nerve $\operatorname{Nrv(S)}$

## Delaunay Triangulations

Given a finite point cloud $V$ in $\mathbb{R}^{n}$,
The Delaunay triangulation of V is a classic notion in Computational Geometry:

* Producing a "nice" triangulation of $V$
* free of long and skinny triangles
* Named after Boris Delaunay for his work on this topic from 1934
* Originally defined for sets of points in $\mathbb{R}^{2}$ but generalizable to arbitrary dimensions

## Delaunay Triangulations

## Definitions:

Given a finite point cloud $V$ in $\mathbb{R}^{2}$,

* The convex hull of V is the smallest convex subset $C H(V)$ of $\mathbb{R}^{2}$ containing all the points of $V$

- A triangulation of V is A 2-dimensional simplicial complex $\boldsymbol{K}$ such that:
* The domain of K is $\mathrm{CH}(\mathrm{V})$
* The 0 -simplices of K are the points in V

## Delaunay Triangulations

## Definition:

A Delaunay triangulation is a triangulation $\operatorname{Del}(\mathrm{V})$ of V such that: the circumcircle of any triangle does not contain any point of V in its interior

## Delaunay Triangulations

## Definition:

A finite set of points $V$ in $\mathbb{R}^{n}$ is in general position if no $n+2$ of the points lie on a common ( $n-1$ )-sphere
E.g. , for $\boldsymbol{n}=\mathbf{2}$,
$V$ in general
position

No four or more points are co-circular

## Theorem:

If $V$ is in general position, then $\operatorname{Del}(V)$ is unique

## Delaunay Triangulations

## Definitions:

The Voronoi region of $u$ in $V$ is the set of points of $\mathbb{R}^{2}$ for which $u$ is the closest

$$
R_{V}(u):=\left\{x \in \mathbb{R}^{2} \mid \forall v \in V, d(x, u) \leq d(x, v)\right\}
$$

* Any Voronoi region is a convex closed subset of $\mathbb{R}^{2}$

4 A Voronoi region is not necessarily bounded

The Voronoi diagram is the collection $\operatorname{Vor}(V)$ of the Voronoi regions of the points of $\vee$

## Delaunay Triangulations

## Duality Property:

If $V$ is in general position, then
the Delaunay triangulation coincides with the nerve of the Voronoi diagram

$$
\operatorname{Del}(V)=\left\{\sigma \subseteq V \mid \bigcap R_{V}(u) \neq \emptyset\right\}
$$

$$
u \in \sigma
$$

* Each point u of V corresponds to a Voronoi region Rv(u)
* Each triangle $t$ of $\operatorname{Del}(V)$ correspond to a vertex in $\operatorname{Vor}(V)$
* Each edge $e=(u, v)$ in $\operatorname{Del}(V)$ corresponds to an edge shared by the two Voronoi regions $R_{V}(u)$ and $R_{V}(v)$

## Delaunay Triangulations

## Algorithms:

+ Two-step algorithms:
* Computation of an arbitrary triangulation $K^{\prime}$
* Optimization of $K^{\prime}$ to produce a Delaunay triangulation
+ Incremental algorithms [Guibas, Stolfi 1983; Watson 1981]:
* Modification of an existing Delaunay triangulation while adding a new vertex at a time
+ Divide-and-conquer algorithms [Shamos 1978; Lee, Schacter 1980]:
* Recursive partition of the point set into two halves
* Merging of the computed partial solutions
+ Sweep-line algorithms [Fortune 1989]:
* Step-wise construction of a Delaunay triangulation while moving a sweep-line in the plane

## Delaunay Triangulations

## Watson's Algorithm:

A Delaunay triangulation is computed by incrementally adding a single point to an existing Delaunay triangulation

Let $V_{i}$ be a subset of $V$ and let $u$ be a point in $V \backslash V_{i}$,

## Input:

$\operatorname{Del}\left(\mathrm{V}_{\mathrm{i}}\right)$, a Delaunay triangulation of $\mathrm{V}_{\mathrm{i}}$

## Output:

$\operatorname{Del}\left(\mathbf{V}_{\mathrm{i}+1}\right)$, a Delaunay triangulation of $\mathbf{V}_{\mathrm{i}+1}:=\mathrm{V}_{\mathrm{i}} \cup\{\mathbf{u}\}$

## Delaunay Triangulations

## Watson's Algorithm:

Given a Delaunay triangulation $\operatorname{Del}\left(V_{i}\right)$ of $V_{i}$ and a point $u$ in $V \backslash V_{i}$,

* The influence region $R_{u}$ of a point $u$ is the region in the plane formed by the union of the triangles in Del( $V_{i}$ ) whose circumcircle contains $u$ in its interior
* The influence polygon $P_{u}$ of $u$ is the polygon formed by the edges of the triangles of $\operatorname{Del}\left(V_{i}\right)$ which bound $R_{u}$

## Delaunay Triangulations

## Watson's Algorithm:

- Step 1:

Deletion of the triangles of $\operatorname{Del}\left(\mathrm{V}_{\mathrm{i}}\right)$ forming the influence region $R_{u}$

+ Step 2:
Re-triangulation of $R_{u}$ by joining $u$ to the vertices of the influence polygon $\mathrm{P}_{u}$

## Delaunay Triangulations

## Watson's Algorithm:

Let $N_{i}=\left|\mathrm{V}_{\mathrm{i}}\right|$

* Detection of a triangle of $\operatorname{Del}\left(V_{i}\right)$ containing the new point $u: O\left(N_{i}\right)$ in the worst case
* Detection of the triangles forming the region of influence through a breadth-first search: O(|Rul)
* Re-triangulation of $P_{u}$ is in $O\left(\left|P_{u}\right|\right)$
* Inserting a point u in a triangulation with $N_{i}$ vertices: $O\left(N_{i}\right)$ in the worst case
* Inserting all points of $\mathrm{V}: O\left(\mathrm{~N}^{2}\right)$ in the worst case, where $\mathrm{N}=|\mathrm{V}|$

## Čech Complexes

## Definition:

$$

In practice, infeasible construction

## Vietoris-Rips Complexes

## Definition:

Given a finite set of points $V$ in $\mathbb{R}^{n}$,

The Vietoris-Rips complex $V R(r)$ of $V$ and $r$ is the abstract simplicial complex consisting of all subsets of diameter at most $2 r$

Formally,

$$
V R(r):=\{\sigma \subseteq V \mid d(u, v) \leq 2 r, \forall u, v \in \sigma\}
$$

## Vietoris-Rips Complexes

## Properties:

- $\check{C} e c h(r) \subseteq V R(r) \subseteq \check{C} e c h(\sqrt{2} r)$

## Vietoris-Rips Complexes

## Properties:

- $\check{C} e c h(r) \subseteq V R(r) \subseteq \check{C} e c h(\sqrt{2} r)$
* VR(r) is completely determined by its 1-skeleton
* I.e. the graph $G$ of its vertices and its edges

## Vietoris-Rips Complexes

## Algorithms:

Input: $\quad \mathrm{A}$ finite set of points V in $\mathbb{R}^{\mathrm{n}}$ and a real positive number r
Output: The Vietoris-Rips complex VR(r)
A two-step approach is typically adopted:

+ Step 1 - Skeleton Computation:
* Exact ( $\mathrm{O}\left(|\mathrm{V}|^{2}\right)$ time complexity )
* Approximate
* Randomized
* Landmarking
* Step 2 - Vietoris-Rips Expansion:
* Inductive
* Incremental
* Maximal

## From Data to Complexes

## Alpha-Shapes

## Definition:

Given a finite set of points V in general position of $\mathbb{R}^{\mathrm{n}}$, let us consider:

* $A_{u}(r):=B_{u}(r) \cap R_{v}(u)$, the intersection of the closed ball with center $u \in V$ and radius $r$ and the Voronoi region of $u$
* S, the collection of these convex sets

The alpha-shape Alpha(r) of V of radius $r$ is the nerve of $S$

Formally,

$$
\text { Alpha(r) }:=\left\{\sigma \subseteq V \mid \bigcap_{u \in \sigma} A_{u}(r) \neq \emptyset\right\}
$$

$A_{u}(r) \subseteq B_{u}(r) \square A l p h a(r) \subseteq \check{C} e c h(r)$

## Witness Complexes

## Motivation:

The "shape" of a point cloud can be captured without considering all the input points

## Definitions:

+ Landmarks:
Selected points
* Witnesses:

Remaining points

## Witness Complexes

## Definition:

The witness complex $W(r)$ of radius $r$ is defined by:

* $u$ is in $W(r)$ if $u$ is a landmark
* $(u, v)$ is in $W(r)$ if there exists a witness $w$ such that

$$
\max \{d(u, w), d(v, w)\} \leq m_{w}+r
$$

where $m_{w}$ : = the distance of $w$ from the 2 nd closest landmark

+ the i-simplex $\sigma$ is in $W(r)$ if all its edges belong to $W(r)$
$W_{o}(r)$ is defined by setting $m_{w}=0$ for any witness $w$

$$
W_{0}(r) \subseteq V R(r) \subseteq W_{0}(2 r)
$$

## From Data to Complexes

## Not Only Point Clouds in $\mathbb{R}^{n}$

Most of the presented constructions can be generalized/adapted to the case of a finite collection of elements endowed with a notion of proximity* enabling to cover a wide plethora of datasets
*More properly, a semi-metric, i.e. a distance not necessarily satisfying the triangle inequality

## From Data to Complexes

Not Only Point Clouds in $\mathbb{R}^{n}$

+ Point Clouds:
* Delaunay triangulation
* Čech complexes

* Vietoris-Rips complexes
* Alpha-shapes
* Witness complexes complexes
* Graphs and Complex Networks:
* Flag complexes
+ Functions:
* Sublevel sets

## From Data to Complexes

## Flag Complex of a Weighted Network:

Let $\mathrm{G}:=(\mathrm{V}, \mathrm{E}, \mathrm{w}: \mathrm{E} \rightarrow \mathbb{R})$ be a weighted undirected graph representing a network:

## From Data to Complexes

## Sublevel Sets of Functions

Given a function $f: D \longrightarrow \mathbb{R}$,

- Step 1:

Transform $f: D \rightarrow \mathbb{R}$ into a function $F: K \rightarrow \mathbb{R}$ defined on a simplicial complex $K$
E.g. if $D$ is a point cloud, construct from it a simplicial complex $K$ and define $F$ as

$$
F(\sigma):=\max \{f(v) \mid v \text { is a vertex of } \sigma\}
$$

+ Step 2:
Build the collection $\left\{K^{r}\right\}_{r \in \mathbb{R}}$ of the sublevel sets of $F$ defined as

$$
K^{r}:=\{\sigma \in K \mid F(\sigma) \leq r\}
$$

Notice that $K^{r}$ is a simplicial complex whenever: if $\tau$ is a face of $\sigma$ then $F(\tau) \leq F(\sigma)$

## Topological Persistence:

* Introduction and algebraic formulation of the notion of persistent homology
* Description of an algorithm for computing persistent homology

## Persistent Homology

## Definition:

Intuitively, a filtration $\mathcal{F}$ is a finite "growing" sequence of simplicial complexes

Formally, a filtration $\mathcal{F}$ of a simplicial complex $K$ is a collection of subcomplexes $\left\{K^{p}\right.$ $\}_{p \in \mathbb{R}}$ of $K$ for which, given any $p, q \in \mathbb{R}$ such that $p \leq q$,

$$
K^{p} \subseteq K^{q}
$$

## Persistent Homology

Most of the techniques transforming a dataset into a simplicial complex depending on the choice of a parameter actually produce a filtration $\left\{K^{p}\right\}_{p \in \mathbb{R}}$

Working Assumption:
We can always pretend that parameter $p$ varies over $\mathbb{N}$

## Persistent Homology

## Definition:

Given a filtration $\mathcal{F}:=\left\{K^{p}\right\}_{p \in \mathbb{N}}$, a value $i \in \mathbb{N}$, and a field $\mathbb{F}$, the $i^{\text {th }}$ persistence module $M$ of $\mathcal{F}$ over $\mathbb{F}$ is defined as the finitely generated graded $\mathbb{F}[x]$-module

$$
M:=\bigoplus_{p \in \mathbb{N}} M_{p}
$$

where:

+ $M_{p}:=H_{i}\left(K^{p} ; \mathbb{F}\right)$, the set of homogeneous elements of grade $p$
*The action $x^{q-p} h$ over an element $h$ of grade $p$ is defined as $\mu_{i} p, q(h)$, where:
$* \mu_{i} p, q(h): H_{i}\left(K^{p} ; \mathbb{F}\right) \rightarrow H_{i}\left(K^{q} ; \mathbb{F}\right)$ is the linear map induced by the inclusion $K^{p} \subseteq$ $K^{q}$

## Persistent Homology

Theorem (structure for finitely generated graded modules over a PID):
Any persistence module M can be expressed as

$$
M \cong \bigoplus_{k=1}^{n} \mathbb{F}[x]\left(-r_{k}\right) \oplus \bigoplus_{j=1}^{m}\left(\mathbb{F}[x] /\left(x^{q_{j}-p_{j}}\right)\right)\left(-p_{j}\right)
$$

So, $M$ is completely determined by the collection of values $r_{k}$ and of pairs $\left(p_{j}, q_{j}\right)$ Such descriptors are typically expressed as pairs, called persistence pairs of $M$, of the kind $\left(r_{k}, \infty\right)$ and $\left(p_{j}, q_{j}\right)$

## Persistent Homology

## Intuitively:

Given a filtration $\mathcal{F}:=\left\{K^{p}\right\}_{p \in \mathbb{N}}$, a persistence pair $(p, q) \in \mathbb{N} \times(\mathbb{N} \cup\{\infty\})$ with $p<q$ represents a homological class that is born at step $\mathbf{p}$ and dies at step $\mathbf{q}$

## Persistent Homology

## Intuitively:

Given a filtration $\mathcal{F}:=\left\{K^{p}\right\}_{p \in \mathbb{N}}$, a persistence pair $(p, q) \in \mathbb{N} \times(\mathbb{N} \cup\{\infty\})$ with $p<q$ represents a homological class that is born at step $\mathbf{p}$ and dies at step $\mathbf{q}$

$(2,3)$

## Persistent Homology

## Intuitively:

Given a filtration $\mathcal{F}:=\left\{K^{p}\right\}_{p \in \mathbb{N}}$, a persistence pair $(p, q) \in \mathbb{N} \times(\mathbb{N} \cup\{\infty\})$ with $p<q$ represents a homological class that is born at step $\mathbf{p}$ and dies at step $\mathbf{q}$

(2, $\infty$ ) essential pair

## Persistent Homology

Differently from homology, persistent homology provides a notion of "shape" closer to our everyday perception

It is possible to compare two shapes by comparing their homology groups

## Persistent Homology

Differently from homology, persistent homology provides a notion of "shape" closer to our everyday perception

It is possible to compare two shapes by comparing their ho

## Persistent Homology

Differently from homology, persistent homology provides a notion of "shape" closer to our everyday perception

It is possible to compare two shapes by comparing their ho

In order to better perform the above task, we need:

* Visual and descriptive representations for persistence pairs
* Notions of distance between sets of persistence pairs and stability results

## Bibliography

## Some References:

+ Persistent Homology:

## Visualizing Persistence

## Persistent Homology

(Persistent) Homology allows for assigning to any (filtered) simplicial complex topological information expressed in terms of algebraic structures

Goal:
We address two main questions:

* Can this topological information be characterized in a simpler and "more visualizable" way?
* Is this information stable under small perturbations of the input data?

## Visualizing Persistence

Given a filtration $\mathcal{F}$,

Persistent pairs of $\mathscr{F}$ can be visualized through:
\& Barcodes [Carlsson et al. 2005; Ghrist 2008]

* Persistence diagrams [Edelsbrunner, Harer 2008]
* Persistence landscapes [Bubenik 2015]
* Corner points and lines [Frosini, Landi 2001]
* Half-open intervals [Edelsbrunner et al. 2002]
* $k$-triangles [Edelsbrunner et al. 2002]

## Visualizing Persistence

## Barcodes:

Persistence pairs are represented as intervals in $\mathbb{R}$

$H_{0}$
$H_{1}$

## Visualizing Persistence

Persistence Diagrams: Persistence pairs are represented as points in $\mathbb{R}^{2}$

## Visualizing Persistence

Persistence Diagrams: Persistence pairs are represented as points in $\mathbb{R} \times(\mathbb{R} \cup\{\infty\})$

Formally, a persistence diagram is a multiset

- Points are endowed with multiplicity

## Visualizing Persistence

Both tools visually represent the lifespan of the homology classes:

* Barcode: length of the intervals
* Persistence Diagram: distance from the diagonal

Barcodes and Persistence Diagrams encode equivalent information

## Visualizing Persistence

Barcodes and Persistence Diagrams encode equivalent information

## Visualizing Persistence

## Persistence Landscapes:

Persistence landscapes are statistics-friendly representations of persistence pairs

Given a persistence module M, persistence landscapes

+ Consist of a collection of 1-Lipschitz functions
+ Lie in a vector space
+ Are stable (under small perturbations of the input filtration)

## Visualizing Persistence

## Persistence Landscapes:

Given a persistence module M,

Formally,

$$
\begin{gathered}
\lambda_{i}(x):=\sup \left\{m \geq 0 \mid \beta^{x-m, x+m} \geq i\right\} \\
\text { where } \beta^{p, q}:=\operatorname{dim}\left(\operatorname{Im}\left(\mu^{p, q}: M_{p} \rightarrow M_{q}\right)\right)
\end{gathered}
$$

## Visualizing Persistence

## Persistence Landscapes:

Mean of persistence diagrams is not unique, but ...

Mean of persistence landscapes is well-defined

## Bibliography

## Some References:

+ Persistent Homology:

## Persistence \& Stability

## Stability of Persistence

In order to be adopted in real applicative domains, it is crucial that persistent homology is not affected by noisy data and small perturbations

Stability Result:
By defining distances* for both domains,

Similar
Persistent Homology
*The term "distance" is intended in a broad sense, including pseudo-metrics and dissimilarity measures

## Stability of Persistence

## Distances:

* For the Data in Input:
* Natural pseudo-distance of shapes
* $L_{\infty}$-distance of filtering functions
* Gromov-Hausdorff distance of metric spaces/point clouds
* For the Retrieved Persistent Homology Information:
* Interleaving distance of persistence modules
* Bottleneck (a.k.a. Matching) distance of persistence diagrams
* Hausdorff distance of persistence diagrams
* Wasserstein distances of persistence diagrams

## Stability of Persistence

## Distances for Input Data:

Let $(X, f)$ be a pair such that:

* X is a (triangulable) topological space
* $f: X \rightarrow \mathbb{R}$ is a continuous function

A pair ( $\mathrm{X}, \mathrm{f}$ ) induces a filtration:

$$
+X^{t}:=f^{-1}((-\infty, t])
$$

Image from [Ferri et al. 2015]

## Definition:

The function $f$ is called tame if:
t has a finite number of homological critical values (i.e. the "time" steps in which homology changes)

* For any $k \in \mathbb{N}$ and $t \in \mathbb{R}$, the homology group $H_{k}\left(X^{t}, \mathbb{F}\right)$ has finite dimension

## Stability of Persistence

## Distances for Input Data:

## Definition:

Given two pairs $(X, f)$ and $(Y, g)$, their natural pseudo-distance $d_{N}$ is defined as:

$$
d_{N}((X, f),(Y, g)):=\left\{\begin{array}{l}
\inf _{h \in H(X, Y)}\left\{\max _{x \in X}\{|f(x)-g \circ h(x)|\}\right\} \\
+\infty \quad \text { if } H(X, Y)=\emptyset
\end{array}\right.
$$

where $H(X, Y)$ is the set of all the homeomorphisms between $X$ and $Y$

## Stability of Persistence

## Distances for Input Data:

Working with two functions $\mathrm{f}, \mathrm{g}: \mathrm{X} \rightarrow \mathbb{R}$ defined on the same topological space X , one can simply consider the $L_{\infty}$-distance between $f$ and $g$

$$
\|f-g\|_{\infty}:=\sup _{x \in X}\{|f(x)-g(x)|\}
$$

## Stability of Persistence

## Distances for Input Data:

Given two finite metric spaces $\left(\mathrm{X}, \mathrm{d}_{\mathrm{X}}\right)$, $\left(\mathrm{Y}, \mathrm{d}_{\mathrm{Y}}\right)$ (e.g. two finite point clouds in $\mathbb{R}^{\mathrm{n}}$ ),

## Definitions:

A correspondence $C$ : $X \rightrightarrows Y$ from $X$ to $Y$ is a subset of $X \times Y$ such that the canonical projections $\pi_{X}: C \rightarrow X$ and $\pi_{Y}: C \rightarrow Y$ are both surjective

The distortion dis(C) of a correspondence $C: X \rightrightarrows Y$ is defined as:

$$
\operatorname{dis}(C):=\sup \left\{\left|d_{X}\left(x, x^{\prime}\right)-d_{Y}\left(y, y^{\prime}\right)\right|:(x, y),\left(x^{\prime}, y^{\prime}\right) \in C\right\}
$$

The Gromov-Hausdorff distance $d_{G H}$ between $\left(X, d_{X}\right)$ and $\left(Y, d_{Y}\right)$ is defined as:

$$
d_{G H}(X, Y):=\frac{1}{2} \inf \{d i s(C) \mid C: X \rightrightarrows Y \text { is a correspondence }\}
$$

## Stability of Persistence

## Distances for Persistent Homology Information:

Two persistence modules M and N are called $\varepsilon$-interleaved with $\varepsilon \geq 0$ if there exist $f$ and $g$ such that, for any $p, q \in \mathbb{R}$ with $p \leq q$, the following diagrams commute

## Definition:

Given two persistence modules $M$ and $N$, their interleaving distance $d_{1}$ is defined as:

$$
d_{I}(M, N):=\inf \{\varepsilon \geq 0 \mid \mathrm{M} \text { and } \mathrm{N} \text { are } \varepsilon \text {-interleaved }\}
$$

## Stability of Persistence

## Distances for Persistent Homology Information:

## Definitions:

their bottleneck distance $\boldsymbol{d}_{B}$ and Hausdorff distance $\boldsymbol{d}_{H}$ are defined as:

$$
d_{B}\left(D_{1}, D_{2}\right):=\inf _{\gamma}\left\{\sup _{x \in D_{1}}\left\{\|x-\gamma(x)\|_{\infty}\right\}\right\}
$$

$d_{H}\left(D_{1}, D_{2}\right):=\max \left\{\sup _{x \in D_{1}}\left\{\inf _{y \in D_{2}}\left\{\|x-y\|_{\infty}\right\}\right\}, \sup _{y \in D_{2}}\left\{\inf _{x \in D_{1}}\left\{\|y-x\|_{\infty}\right\}\right\}\right\}$
where $\gamma$ ranges over all bijections from $D_{1}$ to $D_{2}$

## Stability of Persistence

## Distances for Persistent Homology Information:

## Definitions:

Given two persistence diagrams $D_{1}$ and $D_{2}$,

their bottleneck distance $\boldsymbol{d}_{B}$ and Hausdorff distance $\boldsymbol{d}_{H}$ are defined as:

$$
d_{B}\left(D_{1}, D_{2}\right):=\inf _{\gamma}\left\{\sup _{x \in D_{1}}\left\{\|x-\gamma(x)\|_{\infty}\right\}\right\}
$$

$d_{H}\left(D_{1}, D_{2}\right):=\max \left\{\sup _{x \in D_{1}}\left\{\inf _{y \in D_{2}}\left\{\|x-y\|_{\infty}\right\}\right\}, \sup _{y \in D_{2}}\left\{\inf _{x \in D_{1}}\left\{\|y-x\|_{\infty}\right\}\right\}\right\}$
where $\gamma$ ranges over all bijections from $D_{1}$ to $D_{2}$

## Stability of Persistence

## Stability Results:

Given two pairs ( $\mathrm{X}, \mathrm{f}$ ), ( $\mathrm{Y}, \mathrm{g}$ ) of topological spaces and tame functions and $\mathrm{k} \in \mathbb{N}$, let $\mathrm{M}, \mathrm{N}$ be the induced $k^{\text {th }}$ persistence modules and let $\mathrm{D}_{1}, \mathrm{D}_{2}$ be the corresponding persistence diagrams

* $\quad d_{H}\left(D_{1}, D_{2}\right) \leq d_{B}\left(D_{1}, D_{2}\right)$
* $\quad d_{I}(M, N)=d_{B}\left(D_{1}, D_{2}\right)$

## Theorem:

Under the above hypothesis, the following optimal lower bound holds

$$
d_{I}(M, N) \leq d_{N}((X, f),(Y, g))
$$

## Stability of Persistence

## Stability Results:

## Theorem:

Given two tame continuous functions $f, g: X \rightarrow \mathbb{R}$ on a topological space $X, k \in \mathbb{N}$, and $D_{f}, D_{g}$ the induced $k^{\text {th }}$ persistence diagrams,

$$
d_{B}\left(D_{f}, D_{g}\right) \leq\|f-g\|_{\infty}
$$

## Stability of Persistence

## Stability Results:

## Theorem:

Given two finite metric spaces $\left(X, d_{X}\right),\left(Y, d_{Y}\right), k \in \mathbb{N}$, and $D_{X}, D_{Y}$ the $k^{\text {th }}$ persistence diagrams of the filtrations of the Vietoris-Rips complexes generated by $X$ and $Y$,

$$
d_{B}\left(D_{X}, D_{Y}\right) \leq d_{G H}(X, Y)
$$

## Computing Persistence

## Persistent Homology Computation

Topological Data Analysis allows for assigning to (almost) any dataset a collection of features representing a topological summary of the input data

Shape

Features

Goal:

* How to efficiently compute (persistent) homology?
* How to compactly encode simplicial complexes of high dimension and large size?

## Persistent Homology Computation

## Standard Algorithm:

[Zomorodian \& Carlsson 2005]

Compute a reduced boundary matrix for $\left\{\mathrm{K}^{\mathrm{p}}\right\}_{\mathrm{p}}$ from which easily read the persistence pairs

## Persistent Homology Computation

Given a filtered simplicial complex, let us consider its filtering function $f$ :

$$
f(\sigma):=\min \left\{p \mid \sigma \in K^{p}\right\}
$$

Conversely, $K^{p}:=\{\sigma \in K \mid f(\sigma) \leq p\}$

## Total Ordering on $\left\{K^{p}\right\}_{p}$ :

A sequence $\sigma_{1}, \sigma_{2}, \ldots, \sigma_{n}$ of the simplices of $K$ such that:

+ if $f\left(\sigma_{i}\right)<f\left(\sigma_{j}\right)$, then $i<j$
+ if $\sigma_{i}$ is a proper face of $\sigma_{j}$, then $i<j$

## Persistent Homology Computation

Given a filtered simplicial complex, let us consider its filtering function $f$ :

$$
f(\sigma):=\min \left\{p \mid \sigma \in K^{p}\right\}
$$

Conversely, $K^{p}:=\{\sigma \in K \mid f(\sigma) \leq p\}$

## A Possible Choice:

$$
\begin{aligned}
& \text { Set } \sigma<\sigma^{\prime} \text { if: } \\
& +f(\sigma)<f\left(\sigma^{\prime}\right) \\
& +\quad f(\sigma)=f\left(\sigma^{\prime}\right) \text { and } \operatorname{dim}(\sigma)<\operatorname{dim}\left(\sigma^{\prime}\right) \\
& +\quad f(\sigma)=f\left(\sigma^{\prime}\right), \operatorname{dim}(\sigma)=\operatorname{dim}\left(\sigma^{\prime}\right) \text {, and } \sigma \text { precedes } \sigma^{\prime} \text { w.r.t. the lexicographic order of their vertices }
\end{aligned}
$$

## Persistent Homology Computation

## Boundary Matrix:

A square matrix $D$ of size $n \times n$ defined by

$$
D_{i, j}:= \begin{cases}1 & \text { if } \sigma_{i} \text { is a face of } \sigma_{j} \text { s.t. } \operatorname{dim}\left(\sigma_{i}\right)=\operatorname{dim}\left(\sigma_{j}\right)-1 \\ 0 & \text { otherwise }\end{cases}
$$

E.g.

- $D_{4,18}=1$
- $D_{14,18}=1$
- $D_{13,18}=0$

## Persistent Homology Computation

## Reduced Matrix:

Given a non-null column $j$ of a boundary matrix $D$,

$$
\operatorname{low}(j):=\max \left\{i \mid D_{i, j} \neq 0\right\}
$$

A matrix $\boldsymbol{R}$ is called reduced if, for each pair of non-null columns $j_{1}, j_{2}$,

$$
\operatorname{low}\left(j_{1}\right) \neq \operatorname{low}\left(j_{2}\right)
$$

Equivalently, if low function is injective on its domain of definition

The algorithm returns the above reduced matrix $\boldsymbol{R}$

## Persistent Homology Computation

## Retrieving Persistence Pairs:

* For each $i=1, \ldots, n$,
if there exists $j$ such that $\operatorname{low}(j)=i \quad \square \quad[i, j]$ is a pair for $R$
* Once every $i$ has been parsed,
if $i$ is an unpaired value $[i, \infty)$ is a pair for $R$

From pairs of $R$ to the "actual" persistence pairs of $\left\{K^{p}\right\}_{p}$ :
[i, j] corresponds to [f( $\left.\left.\sigma_{i}\right), f\left(\sigma_{j}\right)\right]$
$\left(\right.$ homological degree $=\operatorname{dim}\left(\sigma_{i}\right)$ )
$[i, \infty)$ corresponds to $\left[f\left(\sigma_{i}\right), \infty\right)$

## Persistent Homology Computation

## Persistent Homology Computation

## Persistent Homology Computation

Standard algorithm to compute (persistent) homology [Zomorodian \& Carlsson 2005]:

* Based on a matrix reduction
* Linear complexity in practical cases
* Cubic complexity in the worst case

## Several different strategies:

## Direct approaches:

* Zigzag persistent homology [Milosavljević et al. '05]
* Computation with a twist [Chen, Kerber '11]
+ Dual algorithm [De Silvia et al. '11]
+ Output-sensitive algorithm [Chen, Kerber '13]
+ Multi-field algorithm [Boissonnat, Maria '14]
* Annotation-based methods [Boissonnat et al. '13; Dey et al. '14]

## Distributed approaches:

* Spectral sequences [Edelsbrunner, Harer '08; Lipsky et al. '11]
* Constructive Mayer-Vietoris [Boltcheva et al. '11]
+ Multicore coreductions [Murty et al. '13]
* Multicore homology [Lewis, Zomorodian '14]
* Persistent homology in chunks [Bauer et al. '14a]
* Distributed persistent computation [Bauer et al. '14b]

## Coarsening approaches:

* Topological operators and simplifications [Mrozek, Wanner '10; Dłotko, Wagner '14]
* Morse-based approaches [Robins et al. '11; Harker et al. '14; Fugacci et al. '14]

## Persistent Homology Computation

## Direct Approaches:

## Data Structures

## Encoding Simplicial Complexes

 Issue:It is enough to have a point cloud consisting of at least 30 points for having to deal with an associated filtered simplicial complex of more than a billion of simplices

## Solution:

Development of compact and efficient data structures for encoding arbitrary simplicial complexes

## Encoding Simplicial Complexes

## Outline:

* Which info to be stored?
* Data Structures
\% Simplex-based representations
: Top-based representations
: Operator-driven representations
- Comparisons
* Issues and solutions in adopting top-based representations

## Out Of Scope:

* Data structures for specific classes of complexes
* E.g. manifold or complexes of low dimension

## Encoding Simplicial Complexes

## Data Structure:

The entities which a simplicial complex consists of are:

- its simplices

$$
K=K_{0} \cup K_{1} \cup \ldots \cup K_{d}
$$

where $\mathrm{K}_{\mathrm{i}}$ is the collection of the i -simplices of K

* the topological relations

$$
\mathrm{R}_{\mathrm{i}, \mathrm{j}} \subseteq \mathrm{~K}_{\mathrm{i}} \times \mathrm{K}_{\mathrm{j}}
$$

between the simplices of $K$ encoding the (co-)boundary of each simplex

A data structure for $K$ has to explicitly store a portion of the above information and to (efficiently) retrieve the remaining part

## Encoding Simplicial Complexes

## Topological Relations:

Given an i-simplex $\sigma$ and a j-simplex $\tau$ of K ,

## Encoding Simplicial Complexes

## Store all the entities

## Simplex-based Representations

## Incidence Graph:

The simplicial complex $K$ is encoded via a directed graph $\boldsymbol{G}=(\mathbf{N}, \mathrm{A})$ :

$$
N \hookleftarrow K
$$

$$
(\sigma, \tau) \in A \hookleftarrow(\sigma, \tau) \in R_{i, i+1}
$$

All the relations between simplices can be immediately retrieved The representation size exponentially increases with the complex dimension

## Simplex-based Representations

## Simplex Tree:

The simplicial complex $K$ is encoded via a directed graph $\mathbf{G}=(\mathbf{N}, \mathrm{A})$ :

$$
N \leftrightarrows K
$$

$$
(\sigma, \tau) \in A \hookleftarrow(\sigma, \tau) \in R_{i, i+1} \text { and } I(\sigma)<I(\tau)
$$

where $I(\sigma)$ denotes the maximum value taken by the vertices of $\sigma$ w.r.t. a total order on $\mathrm{K}_{0}$

## Simplex-based Representations

## Simplex Tree:

The simplicial complex $K$ is encoded via a directed graph $\boldsymbol{G}=(\mathbf{N}, \mathrm{A})$ :

$$
N \leftrightarrows K
$$

$$
(\sigma, \tau) \in A \hookleftarrow(\sigma, \tau) \in R_{i, i+1} \text { and } I(\sigma)<I(\tau)
$$

where I( $\sigma$ ) denotes the maximum value taken by the vertices of $\sigma$ w.r.t. a total order on $\mathrm{K}_{0}$

## Top-based Representations

## IA* Data Structure:

The simplicial complex K is encoded via a directed graph $\boldsymbol{G}=(\mathbf{N}, \mathrm{A})$ :

$$
\mathbf{N} \hookrightarrow K_{o} \cup K_{\text {top }} \quad(\sigma, \tau) \in \boldsymbol{A} \longleftrightarrow\left\{\begin{array}{l}
\sigma, \tau \in K_{\text {top }} \text { and }(\sigma, \tau) \in \boldsymbol{R}_{i, i} \\
\tau \in K_{\text {top }} \text { and }(\sigma, \tau) \in
\end{array}\right.
$$

$$
(\sigma, \tau) \in A \hookrightarrow\left\{\begin{array}{l}
\sigma \in K_{\text {top }} \text { and }(\sigma, \tau) \in R_{i, 0} \\
\sigma, \tau \in K_{\text {top }} \text { and }(\sigma, \tau) \in \boldsymbol{R}_{i, i} \\
\tau \in K_{\text {top }} \text { and }(\sigma, \tau) \in
\end{array}\right.
$$

Compact: it explicitly stores just a fraction of the entities of a simplicial complex Not all the relations between simplices are immediately available

## Top-based Representations

## Stellar Tree:

Given a decomposition of $K_{0}$, the simplicial complex $K$ is encoded via a directed graph $G=(N, A)$ :

$$
\mathbf{N} \hookleftarrow\left(K_{0}=V_{1} \cup V_{2} \cup \ldots \cup V_{n}\right) \cup K_{\text {top }} \quad(\sigma, \tau) \in A \hookrightarrow \sigma \in K_{\text {top }} \text { and }(\sigma, \tau) \in R_{i, 0}
$$

plus a map returning, for each $j$, the vertices of $K$ in $V_{j}$ and the top simplices with at least one vertex in $V_{j}$

Compact and highly adjustable (e.g. choice of the decomposition, of the maximum number of vertices in each region)
Not all the relations between simplices are immediately available

## Operator-driven Representations

## Skeleton Blocker:

The simplicial complex $K$ is encoded by storing its 1 -skeleton (i.e. the graph consisting of the 0 - and the 1-simplices) and a map returning, for each 1-simplex $\sigma$, the blockers of $K$ containing $\sigma$, where:

A simplex $\tau$ is a blocker if $\tau$ does not belong to $K$ but all its faces do

Designed for flag complexes (e.g. VR complexes) and edge contraction Too specific: inefficient in any other task

## Encoding Simplicial Complexes

## Top-based vs Simplex-based:

## Encoding Simplicial Complexes

## Possible Issues in Top-based Representations:

Top-based representations are promising data structures for encoding a simplicial complex K

## but, how to ...

* Store information associated to each simplex of $K$ (e.g. labels, gradient, ...)?

Attach information to the top simplices only

* Efficiently perform operators having explicitly stored a fraction of the entities of K?

Re-define the algorithms performing the operators trying to extract the lowest possible amount of non-explicitly stored entities

## Possible Topics for Seminars

Discrete Morse Theory
Study the shape of a space by studying the behavior of a function defined on it

## Possible Topics for Seminars

Image courtesy of [Carlsson \& Zomorodian 2009]

## Multi-Parameter Persistent Homology

What if we consider multiple filtering functions?

## Possible Topics for Seminars

## Persistent Homology \& Networks

Homological Scaffolds: Topological summaries of weighted graphs
Clique Community Persistence: Tracking the evolution of network communities

## Possible Topics for Seminars

## Algorithms \& Implementation

* Efficient computation of Vietoris-Rips complexes and other data-to-complex strategies
* Focus on a specific algorithm for speed-up persistent homology computation
* Use of available software tools for testing persistent homology on various datasets
